Cancer chemoprevention by 2-amino-3-methylimidazo[4,5-f]quinoline (IQ) and 2-amino-1-methyl-6-phenylimidazo[4,5-b]pyridine (PhIP). The hypothesis that carcinogen-activating enzymes are involved in the cancer initiation and promotion has led to the development of a number of promising chemopreventive agents. Since the carcinogenic activity of 2-amino-3-methylimidazo[4,5-f]quinoline (IQ) has been described in animal models, the chemopreventive effect of IQ has been investigated extensively, in particular in prostate cancer. Because IQ is efficiently metabolized to a DNA adduct, we investigated whether IQ was capable of modulating enzymes involved in the formation of DNA adducts. The results presented here show that the formation of adducts between IQ and the DNA of guinea pig liver and human mammary cells is markedly inhibited by histidine, cysteine, glutathione, and S-adenosylmethionine. The results support the view that IQ and its metabolites modulate enzymes involved in the formation of DNA adducts. This inhibition may have relevance for the chemoprevention of bladder and prostate cancer by the dietary carcinogen IQ. $1) / (-3) + 1$. Let d b e - 6 * (-2 - 10) / (-4
