A novel approach to single-cell proteomic analysis. It is of considerable interest to know the proteome of individual cells at the sub-cellular level. However, the classical approach has not been successful for this purpose. Here we use an innovative technology, which can overcome the bottleneck in proteome analysis at the sub-cellular level. The technology is based on the single-molecule observation and is called single-molecule imaging mass spectrometry (SMI-MS). Using SMI-MS, peptide and protein abundance profiles of each individual sub-cellular compartments can be obtained at the single-molecule level. It is of great importance to know the actual single-molecule proteomes of sub-cellular compartments. With this technology, we obtained individual nuclei, mitochondria, and lysosomes proteomes by tandem mass spectrometry, and showed that proteomes of these sub-cellular compartments in cultured cells are quite different. In addition, the novel technology will be also applied to micro-dissected tissues and various body fluids for proteomic analysis.

Synthesis of polyesters by polycondensation of (thio)esters with polycarboxylic acids in a heterogeneous, catalytic system. Poly(thio)esters can be prepared by the polycondensation of (thio)esters with polycarboxylic acids in a heterogeneous system. The heterogeneous catalyst can be recovered and reused several times. The reaction can be conducted in high yield at room temperature and can be scaled to a multigram level. The polyester products are characterized by <sup>1</sup>H-NMR and elemental analysis. In some cases, high yields are obtained at polydispersities of less than 1.0.
