Rats were trained to discriminate between two odours with a brief inter-trial interval of 30 s. The first-trial odour was maintained against a background of a second odour for varying periods of time. At the end of the offset of the first odour, the rats were expected to approach the second odour. Only those rats which approached the second odour for a period of at least the inter-trial interval were tested with an increased odor-offset phase. Such 'approach-tests' could be performed to discriminate between those rats with high and low performance. Increased response variability was found in the rats with poor performance. The variability was correlated with a higher error rate in the response during the second odor-offset. The more volatile the odour, the lower the

performance and the higher the error rate. Increased response variability during the odoroffset is compatible with a failure to re-activate at least a part of the neural system which was already activated in the presence of the first odorant. This is in agreement with the idea that the neural pattern represented by the odor of the first trial is continuously being modified and cannot be equated to a cue. Microfluidics-based chip-on-chip in situ hybridization of DNA oligonucleotide microarrays and digital transcriptional profiling of B lymphocytes. Here, a novel microfluidics-based chip-on-chip strategy is proposed for quantitative analysis of RNA and DNA microarrays. We have demonstrated a series of experiments that demonstrate the suitability of our platform. Firstly, the chip-on-chip is employed for quantitative analysis of DNA microarrays, with very efficient washing steps to remove the redundant unbound probe. Secondly, we have successfully performed digital

I want to make a wic reset in order to use my printer. New version of WIC reset utility tool, WIC reset utility key free download With the increasing size and scope of computing systems, an increasing number of components and peripherals (referred to herein as "components"

for brevity) are connected to a system bus of the computing system. Such components are controlled by the systems bus, and access the computing system in response to requesting access from the systems bus. Each component that accesses the systems bus has a cycle rate that is independent of the cycle rate of the systems bus. In order to guarantee that the particular component will obtain access to the systems bus at the time required, the component requesting access (referred to herein as "the frontend") establishes a pre-emptive cycle relationship with the systems bus by, for example, submitting a cycle request to the systems bus prior to the time at which the component is to be granted access to the systems bus. A given frontend establishes a pre-emptive cycle relationship by submitting a cycle request at a predetermined time. However, the device requested to be granted access to the systems bus may not be available or ready at the predetermined time. This may occur, for example, when the requested device has been idle (i.e., the requested device has been idle for at least the predetermined amount of time). As such, when the requested component is not available at the predetermined time, the pre-emptive cycle

relationship is prematurely terminated.
